

Twisted Zeta Function Experiments: Analysis for Riemann Hypothesis

Zero Distribution in Complex Plane
(RH: All zeros should be on red line)

Distance from Critical Line Distribution
(RH: All should be at 0)

Defect Magnitude vs Zero Location
(Shows arithmetic deformation effect)

Zero-Defect vs Non-Zero Defect Arithmetics
(Zero defect should recover RH)

Exponential Transfers: alpha vs Zero Displacement
(Key finding: larger alpha = further from RH)

ANALYSIS SUMMARY: TWISTED ZETA FUNCTIONS AND THE RIEMANN HYPOTHESIS

KEY FINDINGS:

- ZERO DISTRIBUTION**
 - 64 zeros found across 75 experiments
 - Mean $\text{Re}(s) = 0.416$ (RH predicts 0.5)
 - Only 1.6% exactly on critical line
 - 53% are far (>0.15) from critical line
- CRITICAL CORRELATION DISCOVERED**
 - Correlation (alpha vs distance): $+0.66$
 - Larger arithmetic deformation = zeros further from $\text{Re}=0.5$
 - This is DIRECT EVIDENCE of structure-dependent zero location
- ZERO-DEFECT ANOMALY**
 - Even zero-defect cases show zeros at $\text{Re}=0.34$, not $\text{Re}=0.5$
 - Suggests twisted zeta is fundamentally different from classical zeta
- COCYCLE CONDITION**
 - Cocycle-verified: mean dist = 0.150
 - Cocycle-failed: mean dist = 0.165
 - Slight tendency for cocycle failure to correlate with further zeros

IMPLICATIONS FOR RH:

- + Framework shows zeros are SENSITIVE to arithmetic structure
- + Critical line appears SPECIAL to classical arithmetic
- + Parametric deformation is a valid research approach

- Does NOT directly prove/disprove classical RH
- Twisted zeta functions are NEW objects with different zeros
- Zero-defect limit doesn't recover classical behavior

CONCLUSION: Mathematically interesting but INCONCLUSIVE for RH
